IEA-Task 53 Meeting Palma de Mallorca

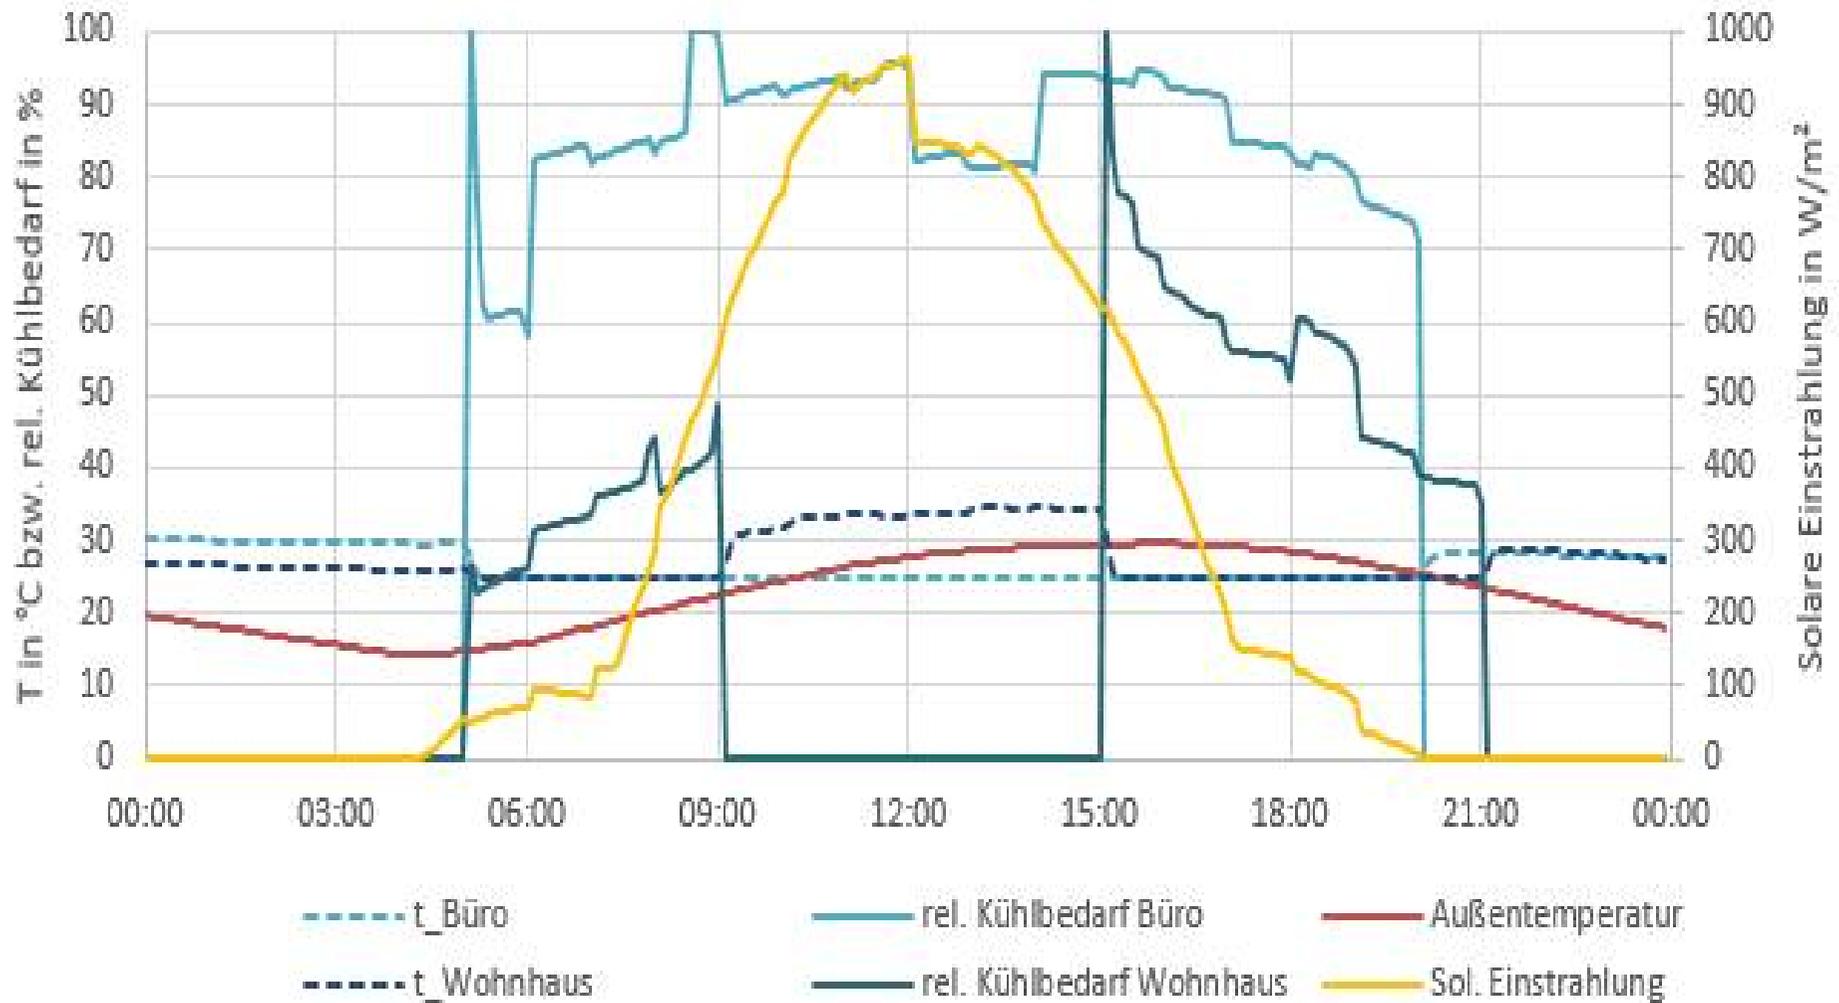

Simulation Results and Experimental Investigations

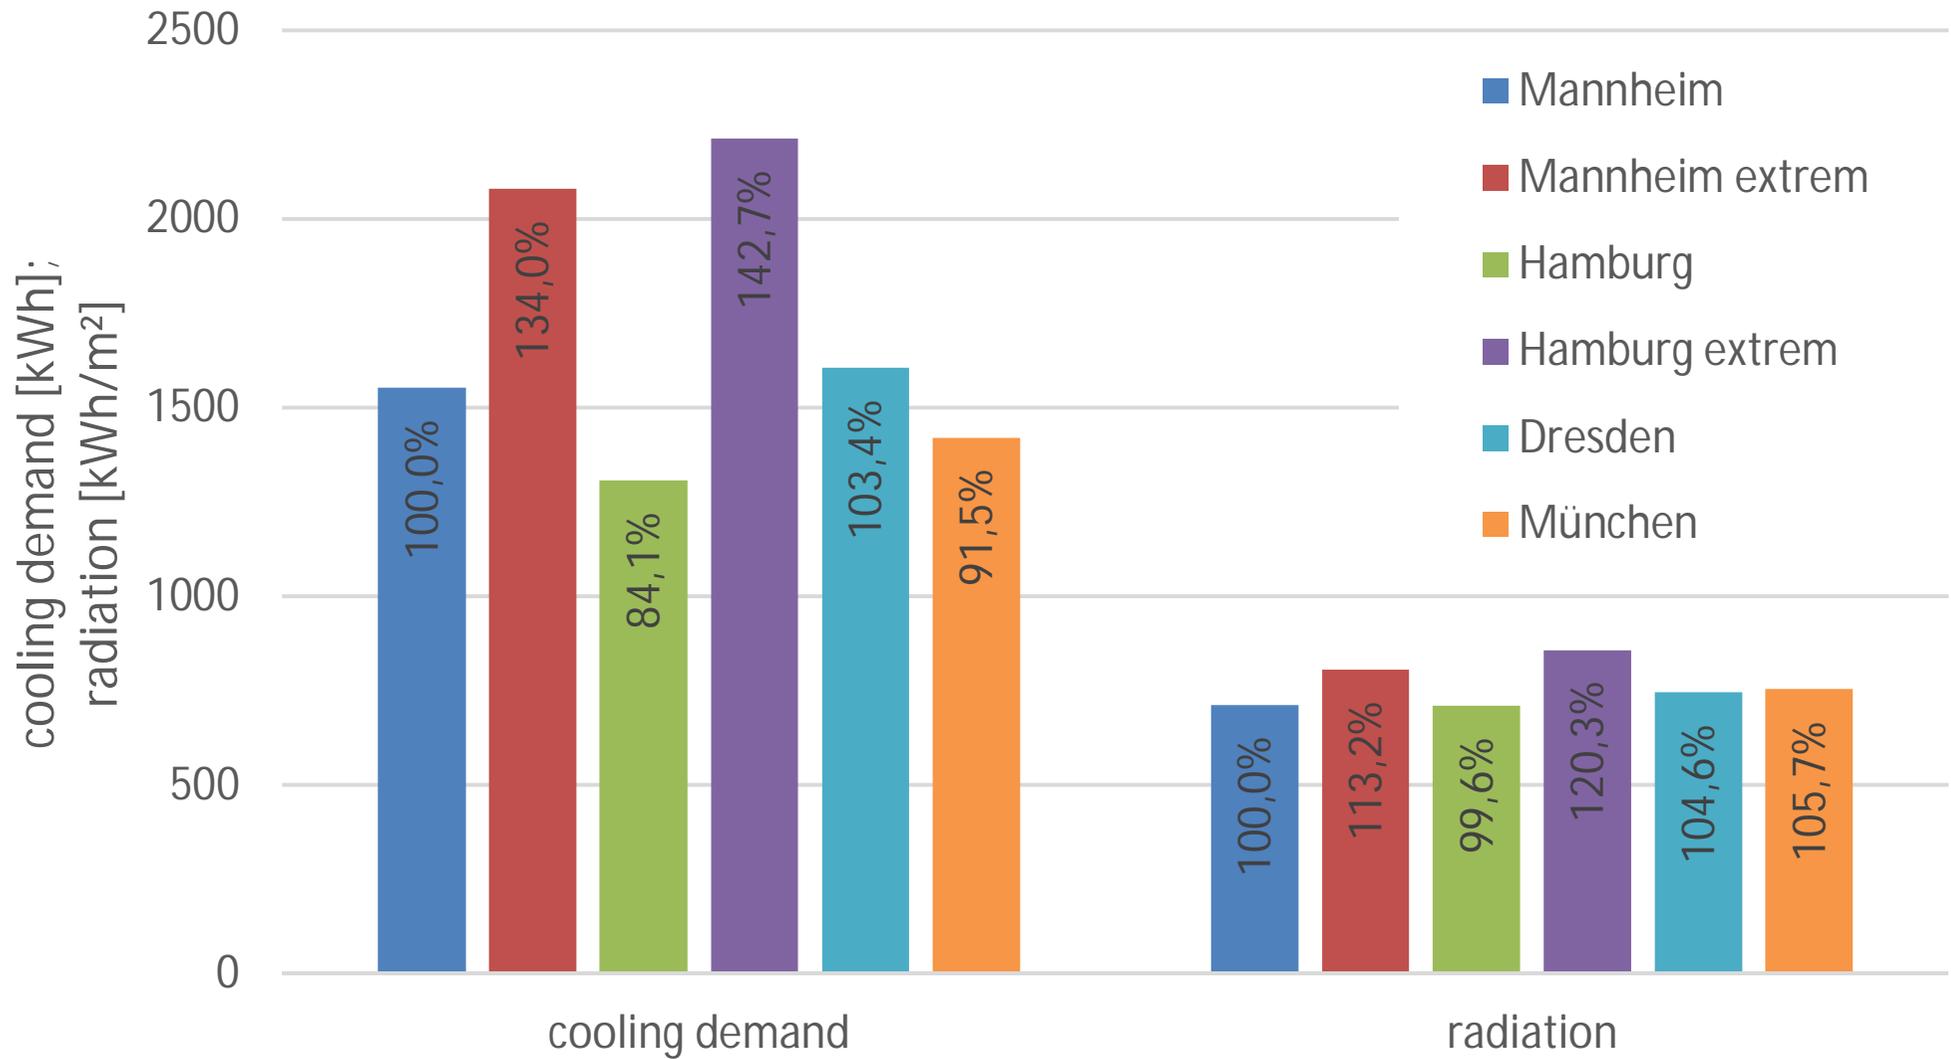

SolarSplit Project – Mono-Split

- ▶ In the first step simulations were carried out to find appropriated ice storage sizes → relevant for a huge number of development actions
- ▶ Building structure was chosen to meet German applications of Mono-Split-Units
- ▶ Two different insulation standards were applied: EnEV2016 and WSchV82
- ▶ Building thermal capacity was studied as cold storage

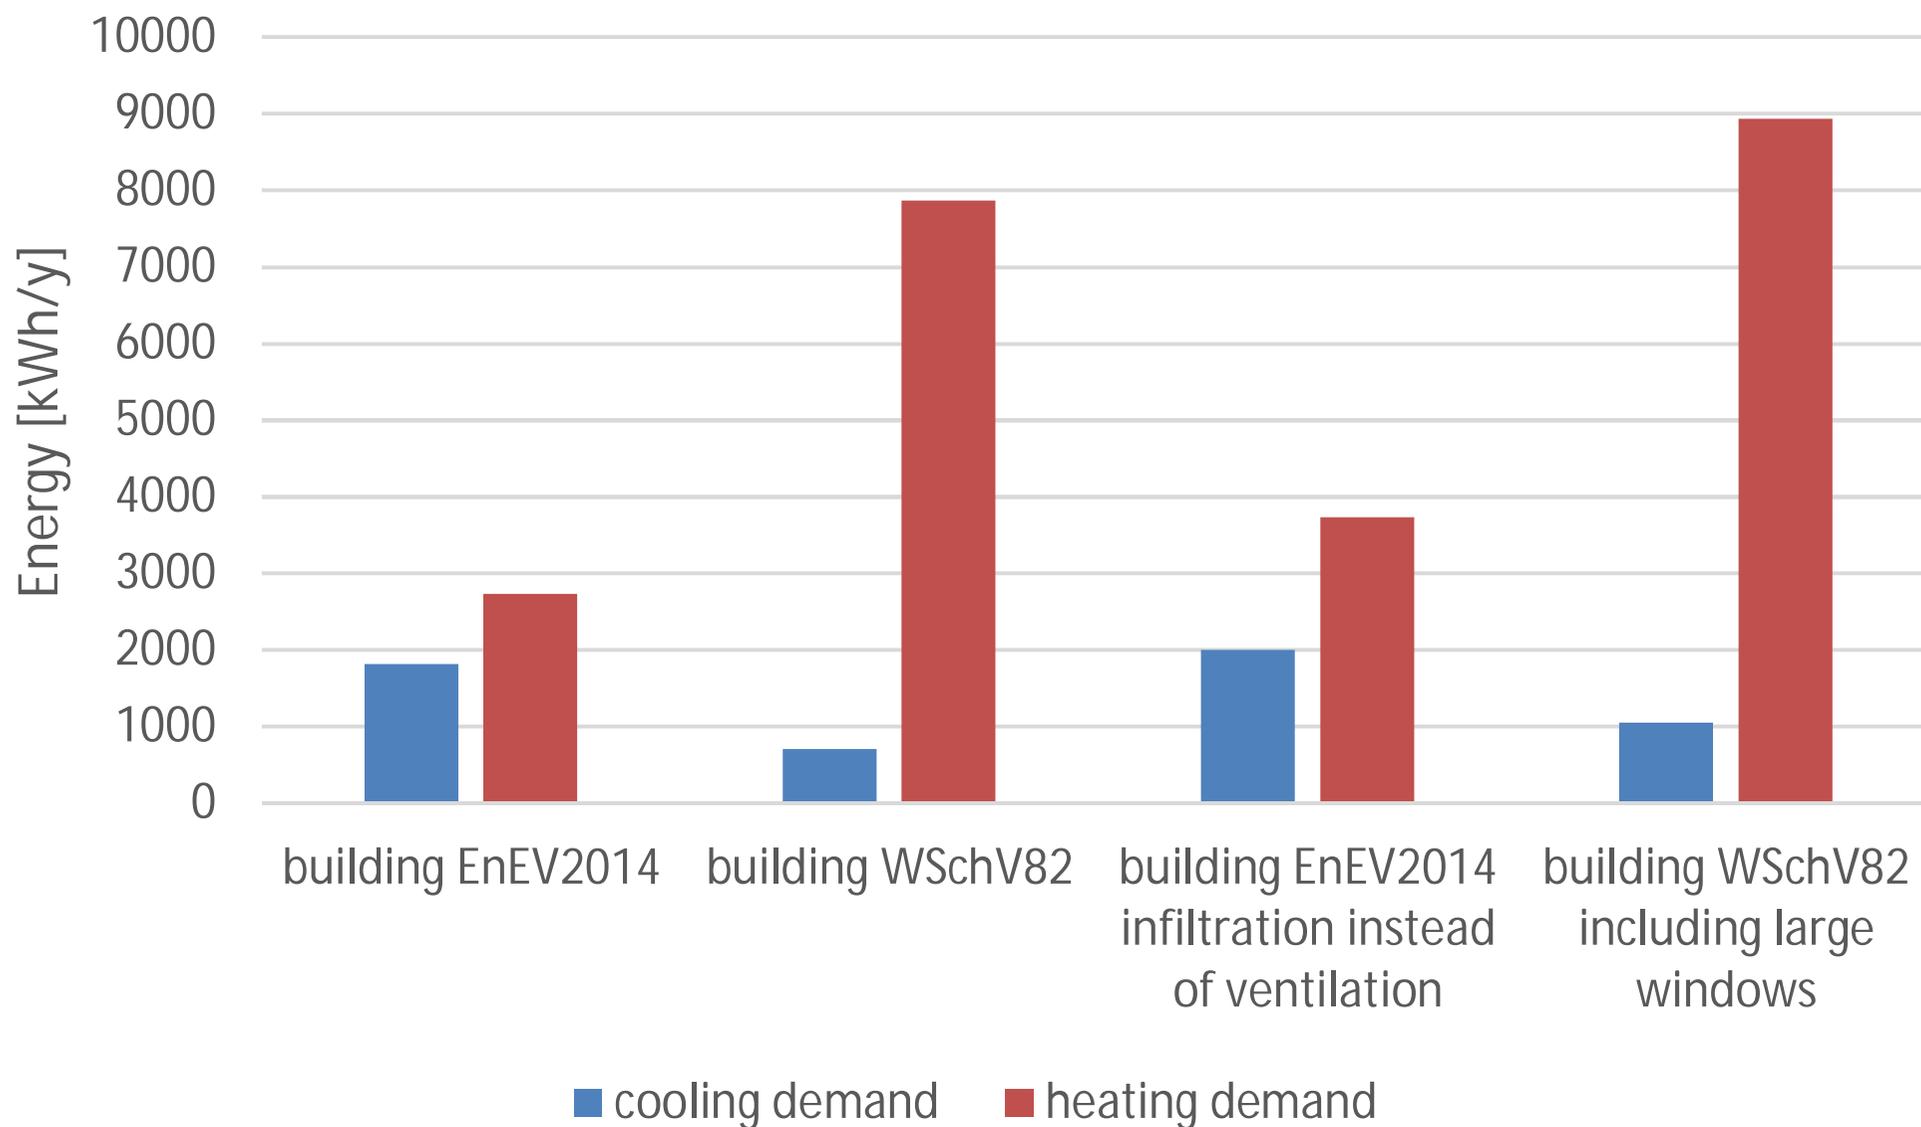

Comparison Single Family House vs. Office Building

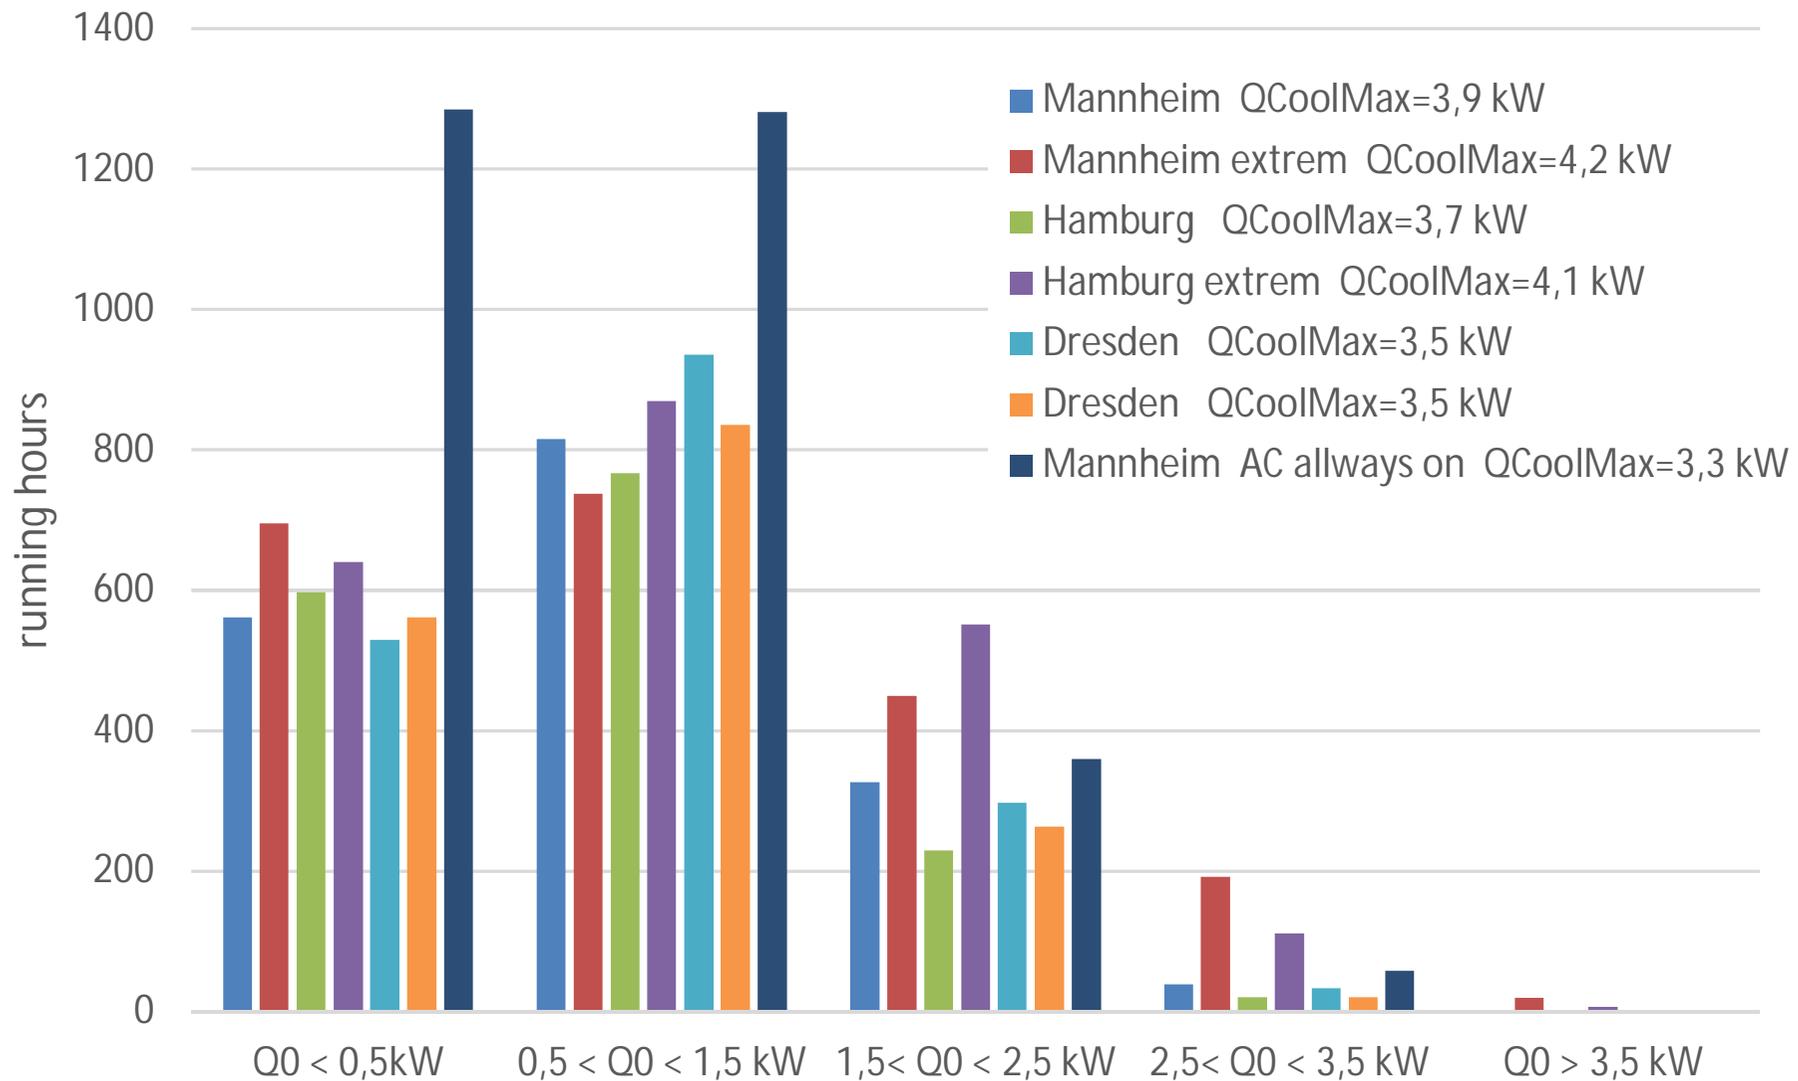

Influence of the insulation level and infiltration / ventilation effect

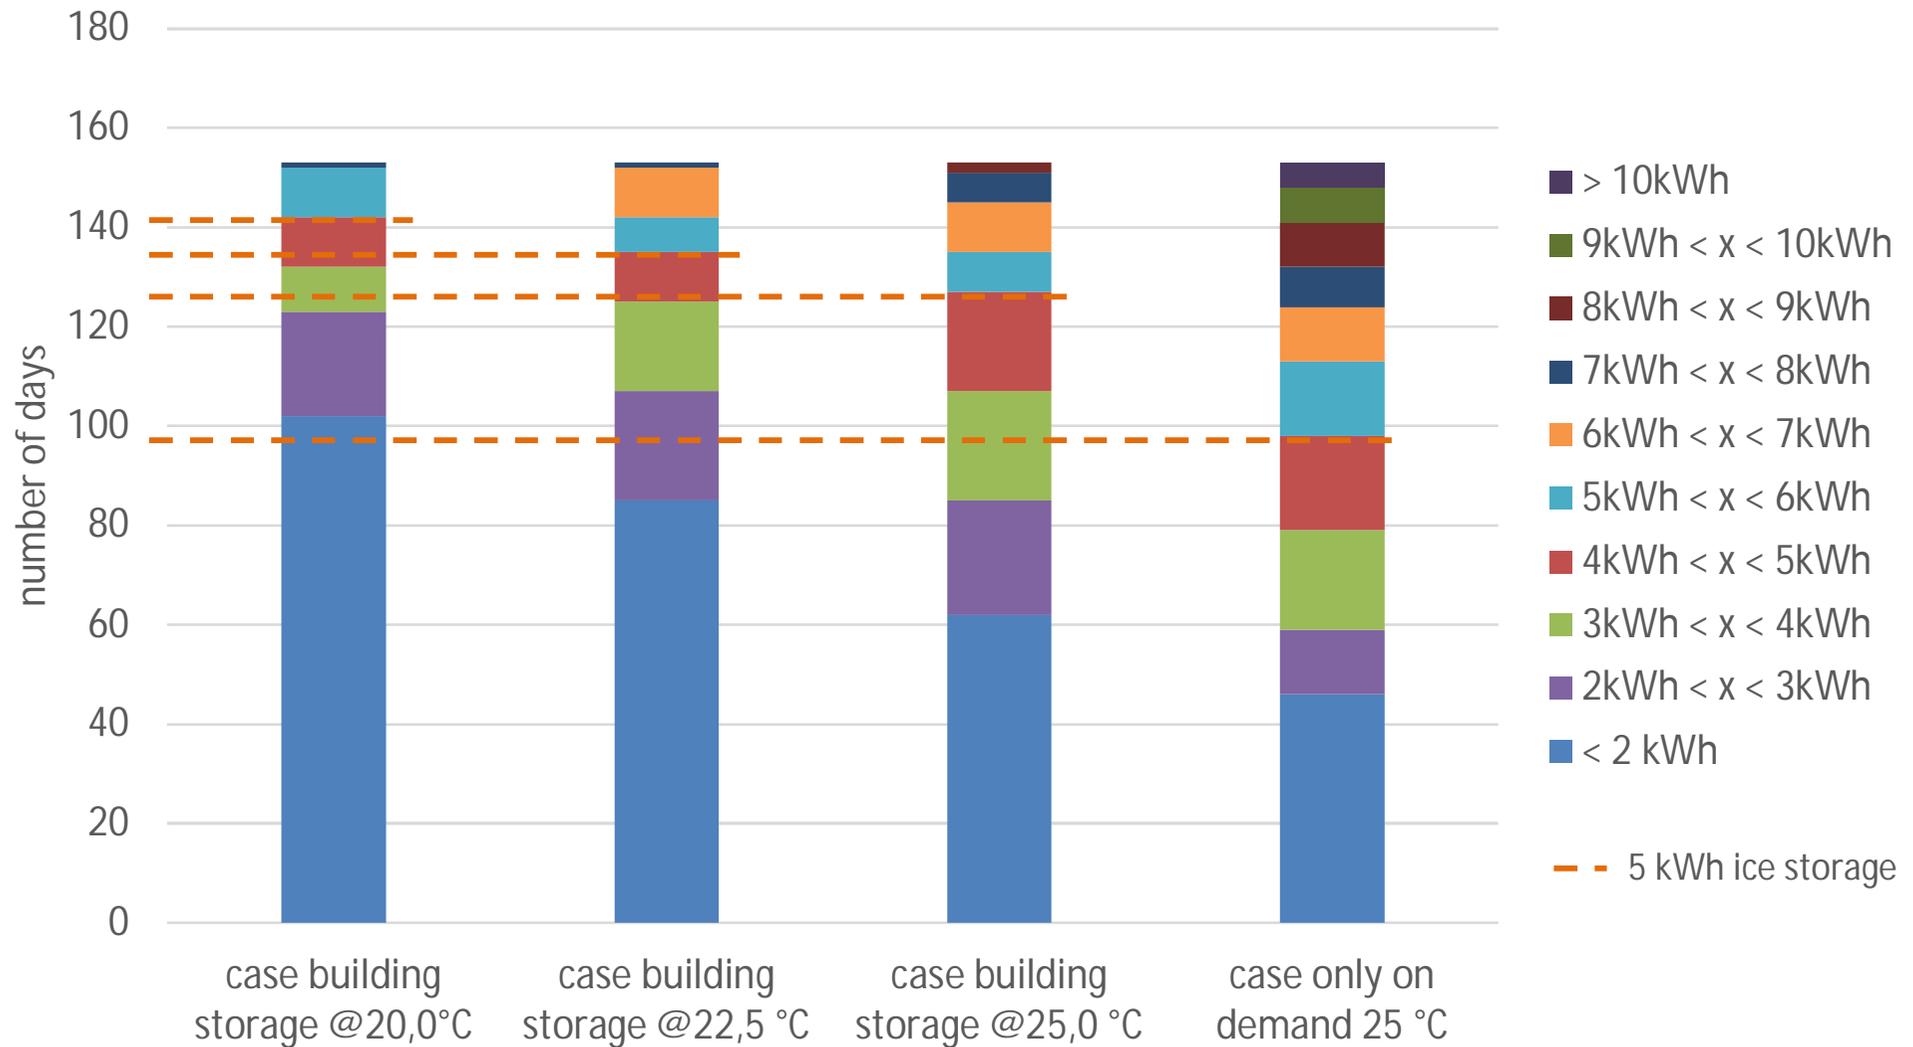

Runing hours AC

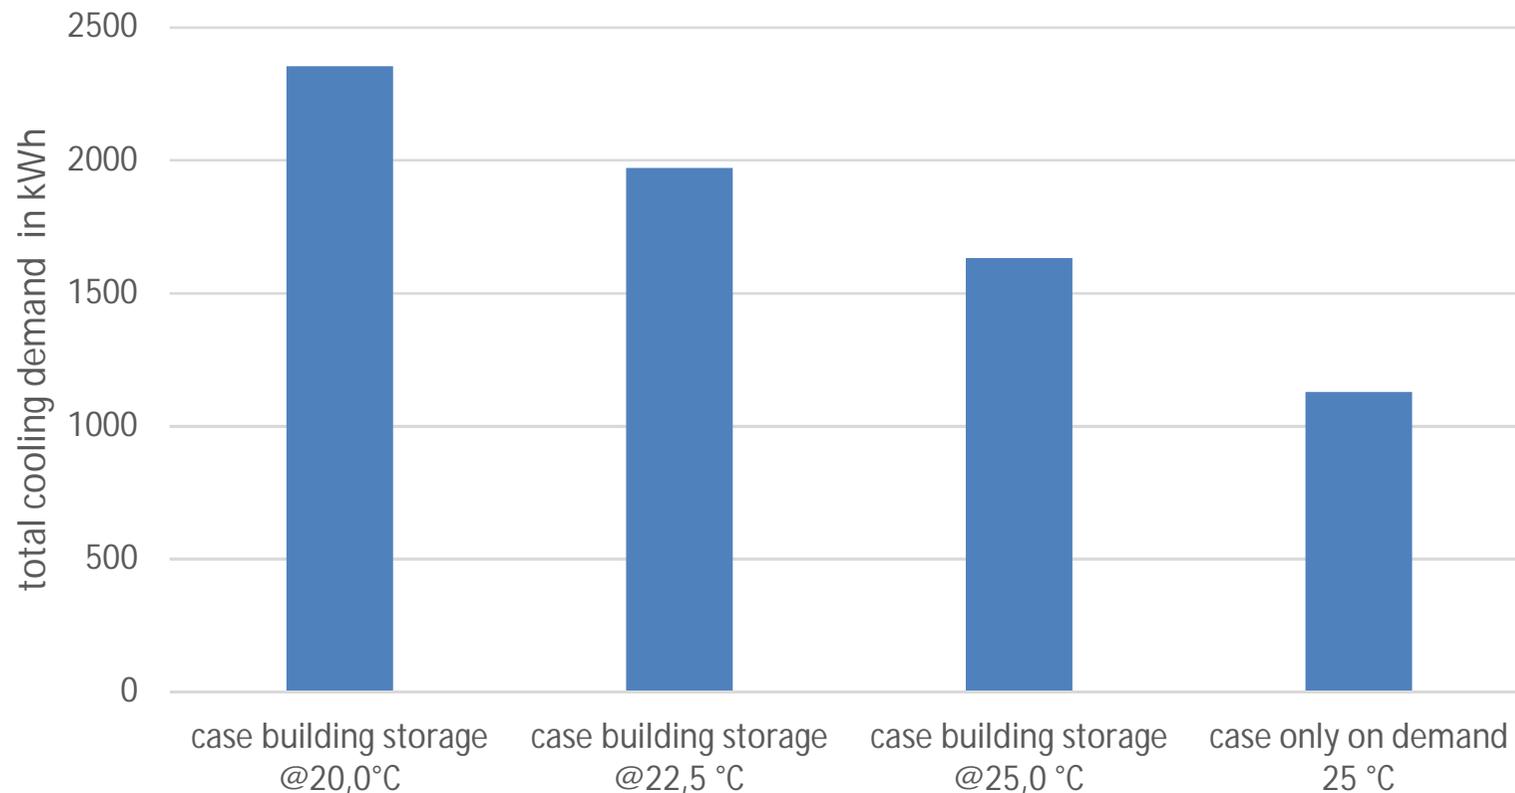

- ▶ **4 different scenarios for sizing the storage**
 - ▶ building is only cooled on demand (then people are present)
 - ▶ building is cooled to 25 °C with energy from PV
 - ▶ building is cooled to 22,5 °C with energy from PV
 - ▶ building is cooled to 20 °C with energy from PV
- ▶ **Storage dimensioning was done by comparing the required cooling energy outside of the PV-production time**

PV-Cooling Days Depending on Cold Storage Size

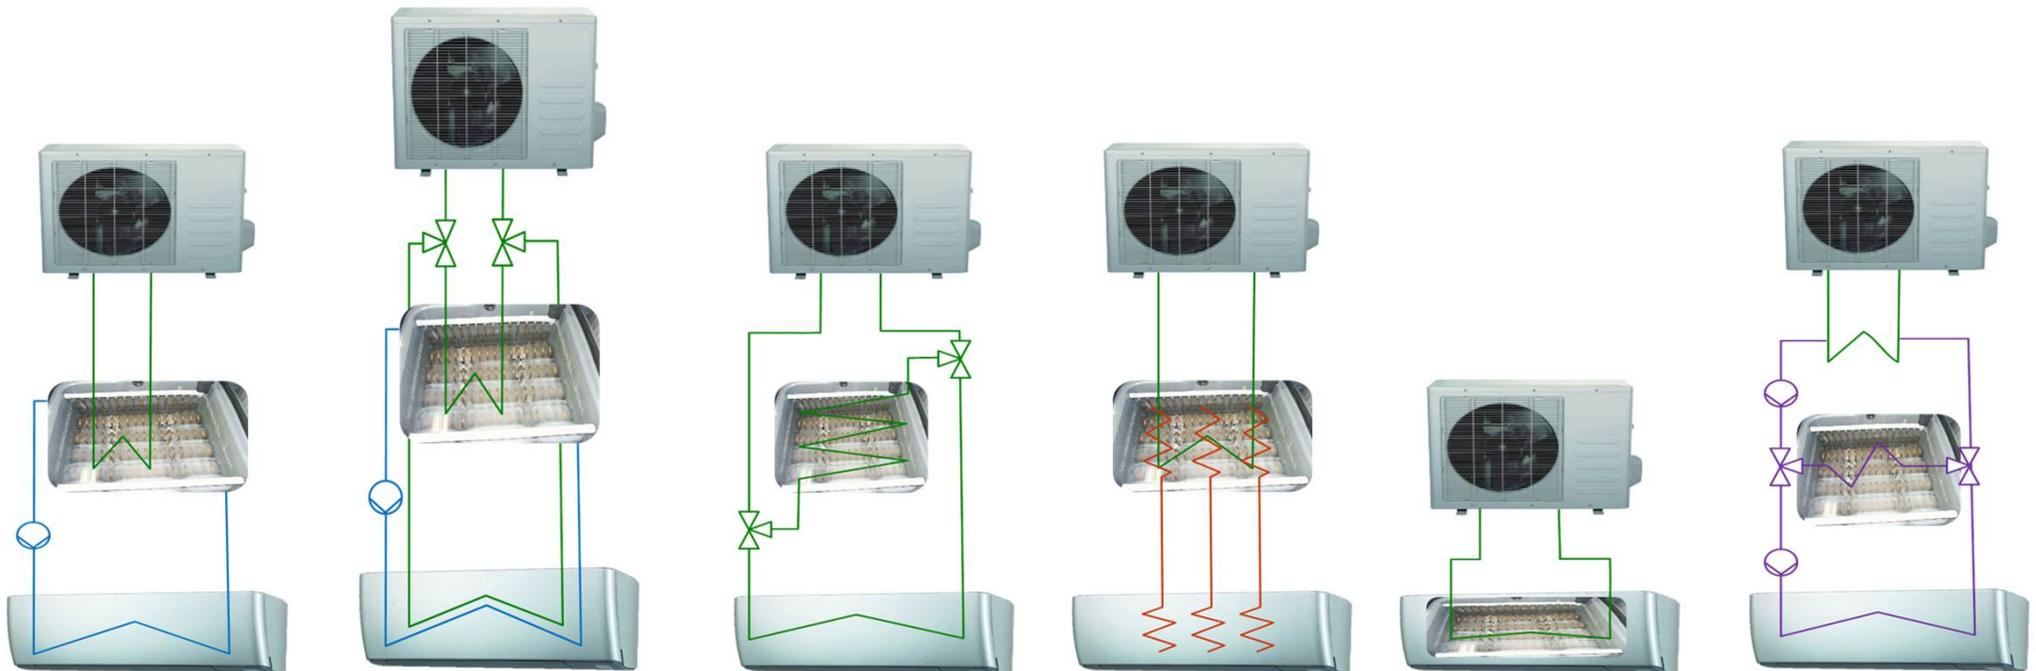

- ▶ **Cool down the building during PV-generation even if no people are present**
- ▶ **Increasing thermal losses**
- ▶ **Without forecast based control → risk of generating heating demand**

Ice Storage Integration Technical Concepts Studied

Experimental Investigation of Mono-Split-Unit with Ice Storage

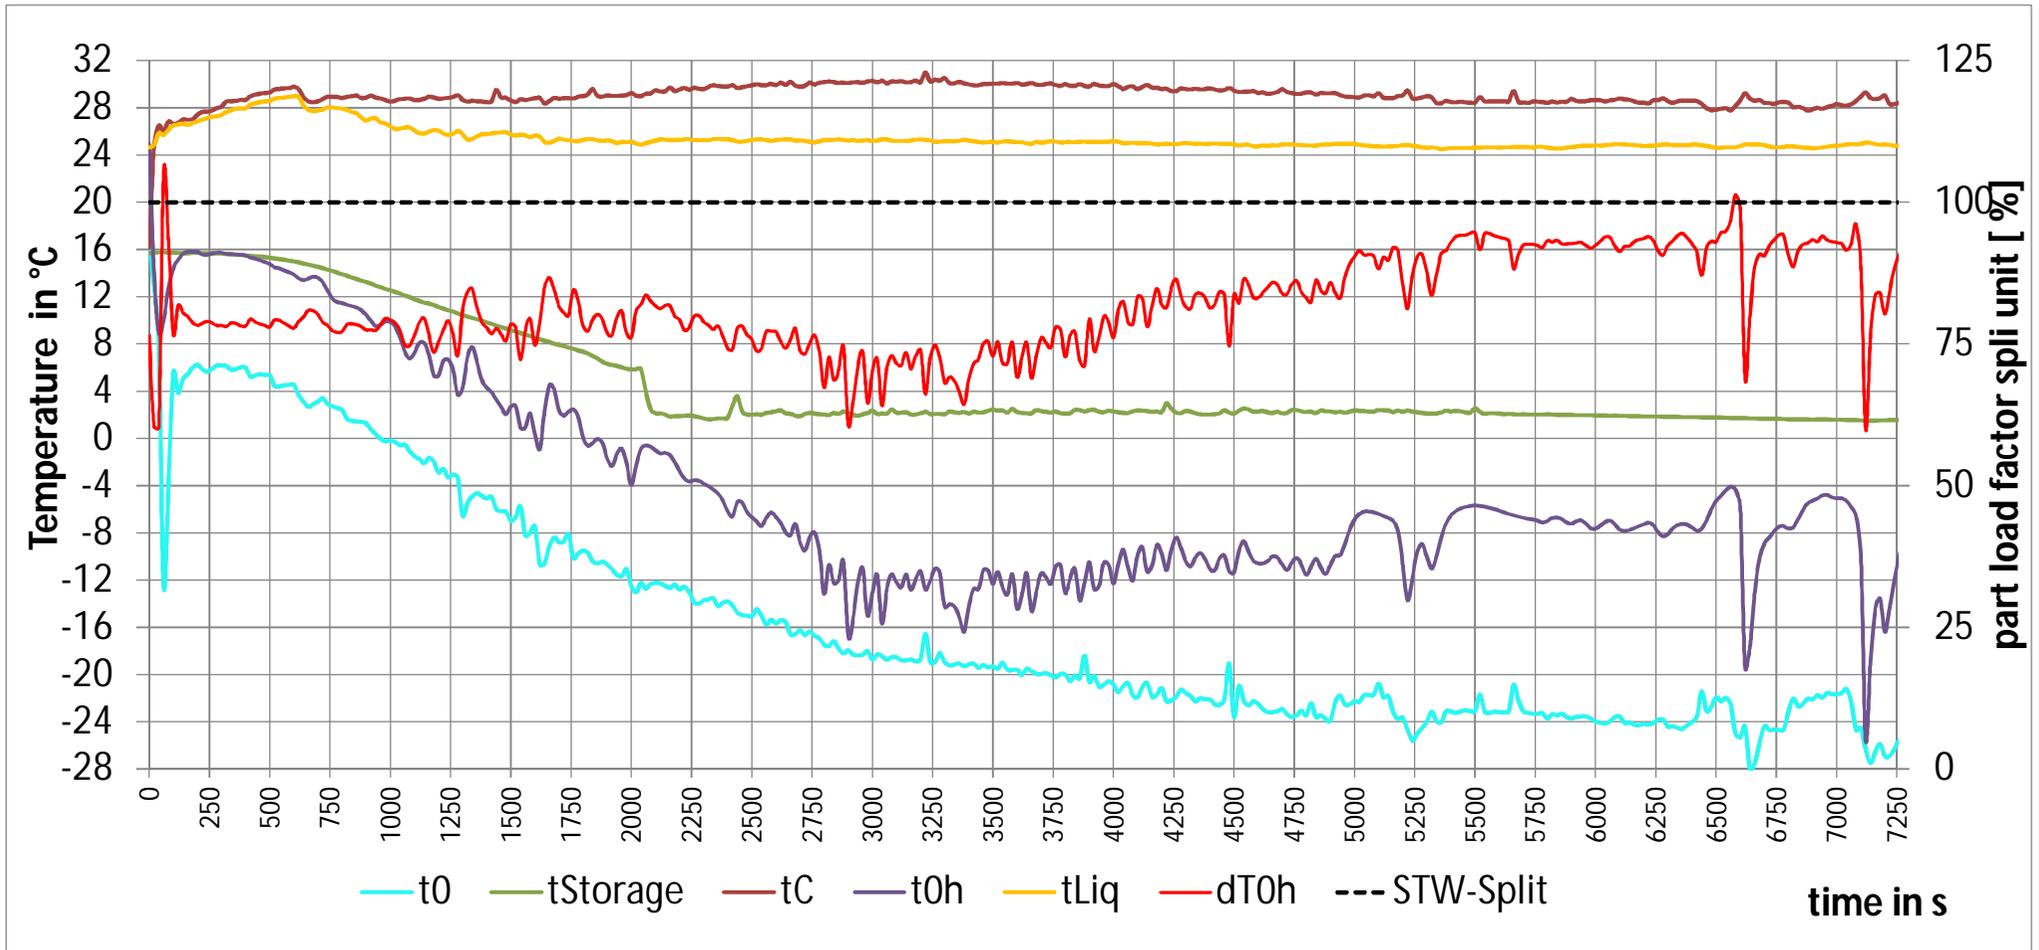

- ▶ Refrigerant charge prediction is done during runtime by observing condenser outlet (→ no gas bubbles) and evaporator outlet (→ stable but not too high super heat)
- ▶ In our first experiments:
 - ▶ condenser outlet never became fully liquid (→ too low charge)
 - ▶ evaporator outlet was in two phase region, no super heat (→ too high charge)

 - ▶ → anti-frost control of split unit avoided lower pressure level in evaporator
 - ▶ only one temperature sensor is used for super heat signal and frost signal

 - ▶ → additional expansion device necessary

Charge Process Temperatures at Full Load
